Unit 4: Measuring GDP and Prices

ECO 120 Global Macroeconomics

1

1.1 Reading

Reading

- Module 10 pages 106-110
- Module 11

1.2 Goals

Goals

- Specific Goals:
 - Understand how to measure a country's output.
 - Learn a way to measure the overall level of prices in the economy.
 - Learn some problems with these measures.
- Learning Objectives:
 - LO3: Define, compute, and explain limitations to measures of the macroeconomy, including gross domestic product, inflation, and unemployment.

2 National income accounts

2.1 Types of Measures

National income accounting

- **National income accounting**: different measures of a country's overall economic performance.
- Why do we care?
 - Assess the health of the economy by comparing output / person across countries and across time periods.

- Track long run growth out the economy.
- Access the effectiveness of macroeconomic policies.
- Measures:
 - Gross domestic product
 - Net domestic product
 - National income
 - Personal income
 - Disposable income

2.2 Gross domestic product

Gross domestic product

- Gross domestic product: total market value of all *final* goods and services produced in a given year.
- To avoid double counting, intermediate goods are not counted.
- Necessary that it be a monetary measure.
- Excludes financial transactions.
- Excludes secondhand sales / sales of used goods.

Example: \$350 suit

- The birth of suit:
 - 1. Sheep rancher produces and sells \$120 wool to a wool processor.
 - 2. A firm processes the wool and sells the material to a suit manufacturer for \$180.
 - 3. The suit manufacturer makes a suit and sells it to a wholesaler for \$200.
 - 4. The wholesaler sells the suit to a retailer for \$250.
 - 5. The retailer sells the suit to you for \$350.
- If we counted all these transactions in GDP we get: 120 + 180 + 200 + 250 + 350 = 1,100.
- When actually, in the end we are only left with a suit worth \$350.

Value added approach

- Add to GDP only the value added at each step:
 - 1. Sheep rancher: \$120
 - 2. Wool processor: \$180 \$120 = \$60
 - 3. Suit manufacturer: 200 180 = 20
 - 4. Wholesaler: \$250 \$200 = \$50
 - 5. Retailer: 350 250 = 100
- Add up the value added at every stage of production: 120 + 60 + 20 + 50 + 100 = 350

What's not counted?

- Non-production transactions: transactions that do not involve production of a good.
- Financial transactions
 - Public transfer payments such as social security payments and veterans payments.
 - Private transfer payments such as gifts between family members.
 - Stock market transactions.
- Secondhand transactions: contribute nothing to production, just moving ownership of final goods between people.

2.2.1 Expenditure approach

Expenditure approach

- **Expenditure approach**: method of computing GDP by adding up all expenditures of final goods and services.
- Consumption: consumption expenditures of households.
- Investment: purchases of capital goods by firms.
- Government purchases.
- Net exports.

Investment

- Gross private domestic investment
 - *Most important:* Capital final purchases of machinery, equipment, and tools.
 - All construction: includes construction of new offices, factories, and residential houses.
 - Changes in inventories: "unsold" output (not counted in consumption, because never purchased).
- Net private domestic investment = gross private domestic investment depreciation.
 - Depreciation: every day some old investment goods need repair or replacement.

Net exports

- **Net exports** = exports imports.
- Export goods are produced in the U.S. and consumed outside the U.S.
- Imports are subtracted
 - Some things in consumption, investment, and government spending may have been imported (not produced in U.S.).
 - Subtracting imports from exports results in a net quantity of goods produced in the U.S. that are sold outside the U.S.

Gross domestic product

Expenditure approach leads to the equation:

$$Y = C + I + G + X - M$$

- Y: total output \equiv GDP.
- C: private consumption
- I: gross private domestic investment
- X: exports
- M: imports

2.2.2 Income approach

Income approach

- **Income approach**: another method of computing GDP, add up total income.
- National income is composed of:
 - Compensation of employees (income earned from labor)
 - Rent (income earned from owning land)
 - Interest (income earned from owning capital)
 - Proprietors' income (income earned from organizing production)
 - Corporate profits (income earned from organizing production)
- National income is *almost* equal to GDP.
 - Requires some statistical adjustments (corporate income taxes, undistributed corporate profits)

Disposable Income

- **Personal income** = National income
 - 1. *minus* social security payments
 - 2. *minus* corporate income taxes
 - 3. minus undistributed corporate profits
 - 4. plus transfer payments
- **Disposable income** = Personal income personal taxes.
- Often, macroeconomist abstract from many of these adjustments and say:

Disposable income $\approx \mathrm{GDP}-\mathrm{Personal}$ Taxes

3 Real GDP

3.1 Real vs. Nominal GDP

Nominal vs. Real GDP

- Problem with GDP calculation is that it measures *market value* of goods and services.
- Prices may increase, but production stay the same.
- Nominal GDP: (unadjusted) GDP calculation using prices that prevailed when output was produced.
- Real GDP: GDP calculation that is adjusted for changes in prices.

- A single measure of the *quantity* of all final goods and services.

3.2 Computing GDP

Calculating Real GDP

- Don't use current year prices to compute real GDP.
- Use prices from a chosen **base year**.
- Example:
 - Suppose only two goods: Brats and Cheese
 - Let's use 2005 as a base year, compute real GDP for 2006

Real GDP₂₀₀₆ = $P_{Brats,2005}Q_{Brats,2006} + P_{Cheese,2005}Q_{Cheese,2006}$

Example: Nominal GDP

	Year 2005		
Item	Quantity	Price	
Brats	100	\$1.00	
Cheese	20	\$5.00	
	Year 2006		
	Year 2	006	
Item	Year 2 Quantity	Price	
Item Brats			

Nominal $\text{GDP}_{2005} = 100(\$1) + 20(\$5) = 200$

Nominal $\text{GDP}_{2006} = 150(\$2) + 25(\$7) = 475$

Example: Real GDP

	Year 2005	
Item	Quantity	Price
Brats	100	\$1.00
Cheese	20	\$5.00
	Year 20	006
Item	Year 20 Quantity	006 Price
Item Brats		

• Real GDP using 2005 as a base year.

Real GDP₂₀₀₅ = 100(\$1) + 20(\$5) = 200Real GDP₂₀₀₆ =

150(\$1) + 25(\$5) = 275

• What is real GDP growth?

Real GDP Growth =
$$\frac{275-200}{200}$$

= 0.375 = 37.5%

Example: Real GDP

	Year 2005		
Item	Quantity	Price	
Brats	100	\$1.00	
Cheese	20	\$5.00	
	Year 2006		
		500	
Item	Quantity	Price	
Item Brats			
	Quantity	Price	

• Real GDP using 2006 as a base year.

Real GDP₂₀₀₅ =
$$100(2) + 20(7) = 340$$

Real
$$GDP_{2006} =$$

 $150(2) + 25(7) = 475$

• What is real GDP growth?

Real GDP Growth =
$$\frac{475-340}{340}$$

= 0.397 = 39.7%

Chain weighted real GDP

- Different base years lead to different conclusions for output growth.
- Chain weighted GDP: Another measure of real GDP that averages out these differences.

3.3 Calculating the Price Level

Calculating the price level

- Price level: an overall measure of prices in the economy.
- **GDP deflator**: average of current year prices as a percentage of base year prices.

$$GDP \text{ deflator} = \frac{\text{Nominal GDP}}{\text{Real GDP}}(100)$$

• Compute GDP deflator using 2005 as a base year.

4 Shortcomings of GDP

Shortcomings of GDP

- Does not account for non-market activities.
- Leisure: Average workweek in 1900 was 53 hours. Today it's 35 hours.
- Improved product quality (eg. computers).
- Underground economy.
- External costs. Clean up costs are actually *added* to GDP.
- Says nothing about distribution.
